Application 1

Comme on disait, le score z pour une valeur est calculé ainsi :

$$z_x = \frac{\mathrm{x} - \mu}{\sigma}$$

Si la moyenne est de 100 et l'écart type est de 15, pour une valeur x de 121.45, l'équation devient :

$$z_x = \frac{121.45 - 100}{15} = 1.43$$

Donc le score z ici est de 1.43.

Si Emma souhaite un partenaire soit dans les 10% (0.1) des hommes les plus intelligents, cela signifie qu'au moins 90% (0.9) soient moins intelligents que son partenaire idéal. On veut donc savoir quel pourcentage se trouve en dessous de 1.43 (ce pourcentage est au moins 90% ou pas ?).

Comme la valeur 121 est plus grande que la moyenne, on regarde le tableau suivant (pour des valeurs plus grandes que la moyenne), la valeur associée à un score z de 1.43. Cette valeur est de 0.9236.

Donc, conformément à la figure associée au tableau, 92,36% (0.9236) des valeurs seront plus petites que 1.43. Cela signifie que Ben est dans les 7.64% (1-0.9236 = 0.0764) les plus intelligents.

Ben remplit donc le critère d'Emma.

Standard Normal Probabilities

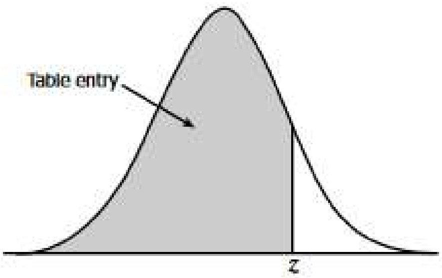

Table entry for z is the area under the standard normal curve to the left of z.

Application 2

Ici, on doit d'abord chercher dans le tableau les scores z et ensuite on doit calculer les deux valeurs qui constitueront la borne inférieure et la borne supérieure de l'intervalle.

L'intervalle pour une probabilité de 95% (0.95) signifie que 5% (0.05) se trouveront en dehors de cet intervalle. Comme la distribution est symétrique, cela signifie que 2.5% (0.025) auront un salaire plus bas que la limite inférieure de l'intervalle, tandis que 2.5% (0.025) auront un salaire plus haut que la limite supérieure de l'intervalle.

Pour calculer la borne inférieure, si l'on cherche dans les valeurs du premier tableau (pour des valeurs plus petites que la moyenne) la valeur 0.025 on voit qu'elle correspond à un score z de -1.96. Le premier calcul devient alors :

$$-1.96 = \frac{\mathrm{x1} - 14.7}{4.2}$$

D'ici, on calcule la valeur de x1 :

$$x1 = (-1.96) * 4.2 + 14.7 = \ \ 6.468$$

Donc, la borne inférieure de l'intervalle est de 6.468$/h et 2.5% (0.025) des salaires sont plus bas que 6.468$/h.

Pour calculer la borne supérieure, si 2.5% (0.025) auront un salaire plus haut que la limite supérieure de l'intervalle, cela veut dire que 97.5% (0.975) auront un salaire plus petit que cette limite supérieure.

Pour la calculer, si l'on cherche dans les valeurs du deuxième tableau (pour des valeurs plus grandes que la moyenne), la valeur 0.975 correspond à un score z de 1.96. Le deuxième calcul devient alors :

$$1.96 = \frac{\mathrm{x1} - 14.7}{4.2}$$

D'ici, on calcule la valeur de x1 :

$$x1 = 1.96 * 4.2 + 14.7 = \ \ 22.932$$

Donc, la borne supérieure de l'intervalle est de 22.932$/h et 2.5% (0.025) des salaires sont plus élevés que 22.932$/h.

Donc, si 2.5% (0.025) des salaires sont plus bas que 6.468$/h et 2.5% (0.025) des salaires sont plus élevés que 22.932$/h, cela signifie que le reste 95% (0.95) des salaires sont situés entre 6.468$/h et 22.932$/h. Donc, avec une probabilité de 95%, le salaire de Noah sera entre 6.468$/h et 22.932$/h.
